

IMPLEMENTATION REVIEW

System Objective Assessment

Ohaiyo Japan inventory, sales, notifications, and reporting modules

Assessment date: October 8, 2026

Scope: current application code and automated tests

Overall: Partially achieved

Product/inventory management and the staff point-of-sale flow are substantially present. Notifications and report actions remain incomplete, the owner sales-recording route is broken, and the test suite has one failing example test.

Objective Findings

1. Manage products and stock across three branches**MOSTLY IMPLEMENTED**

Product creation and editing support branch stock, and inventory is represented per branch. The seeder defines Main, Juban, and Masbate branches.

Evidence: ProductController.php; database/seeder/BranchSeeder.php; database/migrations/2026_08_08_041259_create_inventories_table.php

Risks: The inventory schema has no composite unique constraint for product and branch. The product listing also inserts an unvalidated request branch_id into a raw SQL expression.

2. Record sales transactions efficiently**POS IMPLEMENTED; OWNER ROUTE BROKEN**

Staff checkout validates payment and stock, records the sale and sale items transactionally, locks inventory, and decrements the selling branch stock. The owner sales-recording URL points to SalesController::index, which does not exist; the controller store method has no POST route.

Evidence: StaffSalesController.php; routes/web.php; SalesController.php

3. Notify users about product updates and status**NOT IMPLEMENTED END TO END**

The SMS screen is currently a UI mock-up. Its controller only loads the page, the compose form has no working action or named fields, and the message counters/history are static. The sms_logs table stores timestamps only. No automatic product/status notification workflow was found.

Evidence: SmsController.php; resources/views/owner/sms.blade.php; database/migrations/2026_08_08_041405_create_sms_logs_table.php

IMPLEMENTATION REVIEW

Remaining Objectives

4. Generate sales transactions and inventory reports

LIVE SUMMARIES; ACTIONS INCOMPLETE

Sales and inventory pages calculate current totals from database records, and branch performance aggregates sales by branch. However, report filters are not wired to query parameters, export buttons have no handlers, and the sales chart area is a placeholder. Reports are rendered when opened, but no scheduled/exportable report generation was found.

Evidence: SalesController.php; InventoryController.php; resources/views/owner/reports/sales.blade.php; resources/views/owner/reports/inventory.blade.php

5. Evaluate the system

INITIAL AUTOMATED TESTS ONLY

Automated tests exercise checkout stock decrement, insufficient stock rejection, free items, and manual stock adjustment. Product/branch workflows, notifications, and report behavior lack focused coverage.

6 passed / 1 failed

The failing default ExampleTest expects GET / to return 200, but the application redirects / to /login and returns 302.

Evidence: tests/Feature/UniqueInventoryAvailabilityTest.php; tests/Feature/ExampleTest.php; php artisan test

Priority Follow-up

1. Fix the branch filter SQL. Validate branch_id as an integer and use a bound SQL parameter rather than concatenating request input into orderByRaw.

2. Enforce role-based route access. Owner and staff route groups currently declare auth middleware only; apply role authorization to prevent cross-role access to product and administration actions.

1. Repair the owner sales-recording route and add tests for its transaction and inventory behavior.
2. Implement real notification sending, product/status triggers, and persistent message delivery logs.
3. Connect report filters to controller queries; implement exports or remove inactive controls and placeholder chart content.
4. Add a unique database constraint for inventory (branch_id, product_id), after checking and resolving any existing duplicates.
5. Expand tests to cover three-branch product and stock workflows, role access, report filters, and notification behavior.

Prepared from the current workspace code and test run. This is an implementation-status assessment, not a production security audit.
